# **Background**

To maximize power adaptations, resistance training (RT) should be performed at maximal power output. In sports where more than one training bout is necessary in a day, subsequent RT may be limited by muscle glycogen, resulting in lower power output. High molecular weight (HMW) carbohydrate (CHO) solutions have been shown to result in greater glycogen re-synthesis rates, and greater work output during a subsequent cycling time trial compared to a low molecular weight (LMW) CHO solution. However, the effect of a HMW CHO on RT power output following exhaustive exercise is unknown.

## Methods

Sixteen resistance trained men (mean  $\pm$  SD; 23  $\pm$  3 years;  $176.7 \pm 9.8$  cm;  $88.2 \pm 8.6$  kg;  $12.1 \pm 5.6\%$  fat) participated in this study. One-repetition maximum (1RM) back squat (153.3  $\pm$  53.6 kg; 1.7  $\pm$  0.2 1RM:body mass), and  $VO_2$  max (37.4 ± 4.3 ml·kg·min<sup>-1</sup>) were initially assessed in order to prescribe exercise intensities during experimental trials. In a double-blind, placebo-controlled, randomized cross over design consisting of three testing sessions separated by one week, subjects completed a glycogen depleting exercise bout on a cycle ergometer. Immediately post-exercise, subjects ingested a placebo (PLA), or a LMW or HMW CHO solution (10%) providing 1.2 kg· bw-1 CHO, assigned randomly. Two hours post-ingestion, subjects performed 5 sets of 10 repetitions back squat (75% 1RM) "as explosively as possible". If subjects paused for more than 2 seconds or were unable to complete a rep, resistance was lowered by 13.6 kg. Kinematic and kinetic measurements were sampled at 1000 Hz via force plate and two linear position transducers.

#### Results

Average power following ingestion did not differ between CHO solutions until Set 4 (p = 0.108) and Set 5 (p =0.083). Average power collapsed across the latter Sets was greater following ingestion of the HMW solution (Set 4, 1216 ± 97 W; Set 5, 1143 ± 102 W) compared to PLA (Set 4, 1066  $\pm$  80 W: p = 0.037; Set 5, 1019  $\pm$  89 W: p = 0.048), but not compared to ingestion of LMW (Set 4, 1160  $\pm$  79 W: p = 0.355; Set 5, 1131  $\pm$  92 W: p = 0.852). No difference was observed between LMW and PLA (Set 4, p = 0.275; Set 5, p = 0.077). The difference in average power was driven by velocity, as similar trends were observed in Set 4 and 5 (p = 0.100 and p = 0.066, respectively). Average velocity was higher following ingestion of HMW (Set 4, 0.63  $\pm$  0.03 m·s<sup>-1</sup>; Set 5, 0.62  $\pm$  $0.03 \text{ m} \cdot \text{s}^{-1}$ ) compared to PLA (Set 4,  $0.56 \pm 0.04 \text{ m} \cdot \text{s}^{-1}$ : p = 0.050; Set 5, 0.56 ± 0.04 m·s<sup>-1</sup>: p = 0.032), but not LMW (Set 4, 0.61  $\pm$  0.03 m·s<sup>-1</sup>; p = 0.422; Set 5, 0.61  $\pm$  $0.03 \text{ m}\cdot\text{s}^{-1}$ : p = 0.074), with no difference between LMW and PLA (Set 4, p = 0.220; Set 5, p = 0.769). HMW conferred a likely beneficial effect in Sets 4 and 5 (92.5% and 88.7% likelihood, respectively), compared to PLA; while ingestion of LMW conferred only a possibly beneficial effect (68.7%) and likely beneficial effect (83.9%) in Sets 4 and 5, respectively.

# **Conclusions**

These data suggest post-exercise ingestion of a HMW CHO solution providing 1.2 kg· bw<sup>-1</sup> CHO may allow
